ExampleA

March 27, 2024

1 Project enda : Example A

In this example notebook, we will show how to read and manipulate contracts data on a small sample. Then we will show how to align it with consumption, weather and TSO forecast data in order to train it and make a load forecast.

To start, you will need a python 3 installation (use a virtual environment), and to install some packages. You can do it using poetry, or pip.

```
# create virtualenv, can use for instance {path_to_python3.9} instead of just "python3"
python3 -m venv {path-to-venv}
source {path-to-venv}/bin/activate
which python # check python path

# install enda with poetry
# next line install required packages to run the examples
poetry install enda

# install enda with pip
pip install enda
# in that case, you'll also need some extra packages,
# such as jupyter to run that notebook, or matplotlib
pip install jupyter numexpr joblib matplotlib
```

Then you can download example_a.zip to your local machine. It contains this note-book (ExampleA.ipynb) and the dataset (contracts.csv, historic_load_measured.csv, weather_and_tso_forecasts.csv). Open ExampleA.ipynb with jupyter and follow the tutorial there instead of the pdf/html. The dataset is a micro-example of the data we typically deal with.

We here pretend we are exactly on '2020-09-20' and want to predict our SLP (synthetic load profiles) customers load for the next 3 days, from '2020-09-21' to '2020-09-23' at a 15 min time-step. The desired time-zone is 'Europe/Berlin'. This load may depend on several factors such as the number of customer or the weather. In this example, we have only 3 days of training data, from '2020-09-16' to '2020-09-19'.

Data from '2020-09-20' is not available because we do not have the most recent measured consumption data: there is a time-gap between the latest time for which we have an actual measure and the next time we want to predict. In a more realistic example, this gap may be a few days or weeks.

The files are: - contracts.csv: contains a list of 7 electricity customer contracts with different characteristics. - historic_load_measured.csv: the past load for 2 groups of customers:

smart_metered and slp, from '2020-09-16' to '2020-09-19'. - weather_and_tso_forecasts.csv: 2 external forecasts, the temperature and the total load on our TSO's grid, available in the past and in the future: from '2020-09-16' to '2020-09-23'.

You can now follow this tutorial step by step. It is divided in 3 parts: 1. Deal with contracts data 2. Make a really basic prediction 3. Try it yourself

```
[1]: import os import pandas as pd import enda
```

```
[2]: enda.__file__
```

[2]: '/Users/clement.jeannesson/Jobs/enda/enda/__init__.py'

```
[3]: # replace with the folder path where you put example_a
DIR = '.'
```

1.1 1. Deal with contracts data

```
[4]: contracts = enda.Contracts.read_contracts_from_file(os.path.join(DIR, user contracts.csv"))
```

```
[5]: contracts

# When date_end_exclusive = NaT, this means the contract is still active today
and has no planned end date.

# Note that lines 1 and 2 are about the same customer with customer_id=1. They
changed their subscribed power,

# so we counted it as a new contract (contract_id=1-a then 1-b).

# Note that some have a start date or an end date in the 'future' (after_
'2020-09-20').
```

```

```

[288 rows x 5 columns]

```
[20]: # create minimalistic features, for the example, just the hour
def featurize(df):
    df = df.copy(deep=True)
    df["hour"] = df.index.hour
    return df
```

```
[21]: slp_historic = featurize(slp_historic)
slp_forecast_input = featurize(slp_forecast_input)
```

In this example we will use a simple linear regression using the implementation in sklearn. Enda has a wrapper that works with any scikit-learn estimator: enda.ml_backends.sklearn_estimator.EndaSklearnEstimator. It makes it easier to deal with timeseries and pandas dataframes. It also allows to use estimators in more advanced models defined in enda.

To save a trained model we will use joblib.

Install the requirements if you haven't already:

pip install scikit-learn joblib

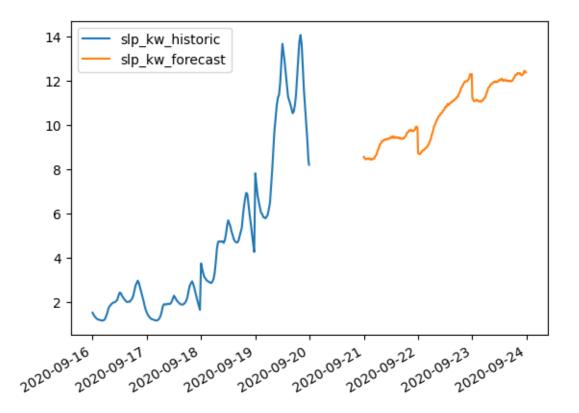

```
[22]: from enda.ml_backends.sklearn_estimator import EndaSklearnEstimator from sklearn.linear_model import LinearRegression import joblib
```

```
[23]: lin_reg = EndaSklearnEstimator(LinearRegression())
lin_reg.train(slp_historic, target_col='slp_kw')
```

```
[24]: # save model to a file
model_path = os.path.join(DIR, "lin_reg.joblib")
joblib.dump(lin_reg, model_path)
del lin_reg
```

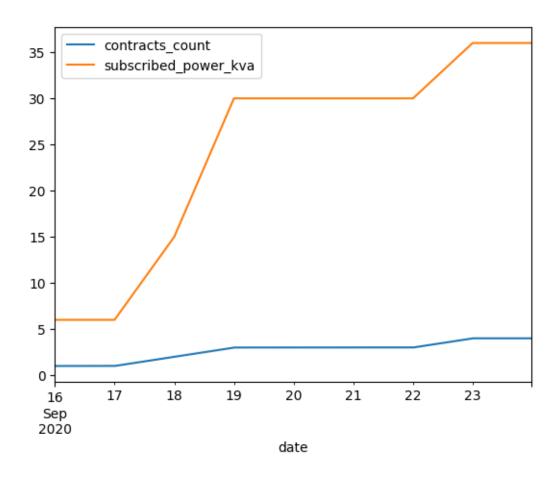

```
[25]: # load model from the file
lin_reg = joblib.load(model_path)
prediction = lin_reg.predict(slp_forecast_input, target_col='slp_kw')
assert (prediction.index == slp_forecast_input.index).all() # verify that the_
pandas.DatetimeIndex is conserved
```

```
[26]: prediction
[26]:
                                     slp_kw

      [288 rows x 1 columns]
     To visualize pandas dataframes, we use matplotlib as backend. Install it if you haven't already:
     pip install matplotlib
[27]: import matplotlib.pyplot as plt
[28]: # plot consumption : historic and forecast
      to_plot = pd.merge(
          slp_historic["slp_kw"].to_frame("slp_kw_historic"),
          prediction.rename(columns={"slp_kw": "slp_kw_forecast"}),
          how='outer', left_index=True, right_index=True
      to_plot.plot()
[28]: <Axes: >
```

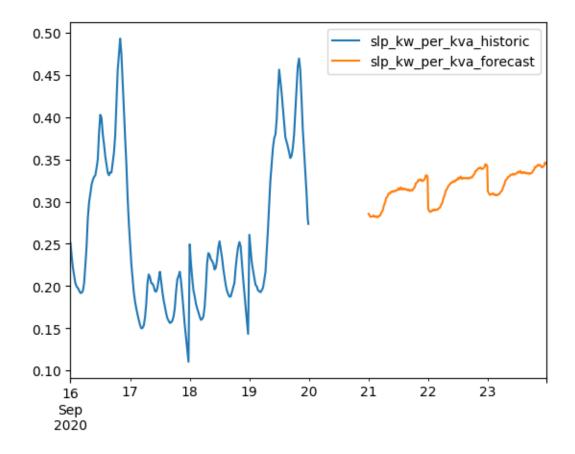

```
[29]: # plot the size of the portfolio of SLP customers over time
portfolio_slp[["contracts_count", "subscribed_power_kva"]].plot()
```

[29]: <Axes: xlabel='date'>

[30]: <Axes: >

1.3 3. Try it yourself

As an exercise, you should repeat the previous analysis/prediction but this time on smart-metered customers.

1.4 Conclusion

Thats all for this introduction. Go to Example B for a more complete and in-depth example. Thanks for reading and don't hesitate to send feeback at: team-data@enercoop.org!
